of Animals SibRAS, Novosibirsk, Russia

# Optimal foraging theory

Peck it? Pass it over?

# Risk-sensitive foraging

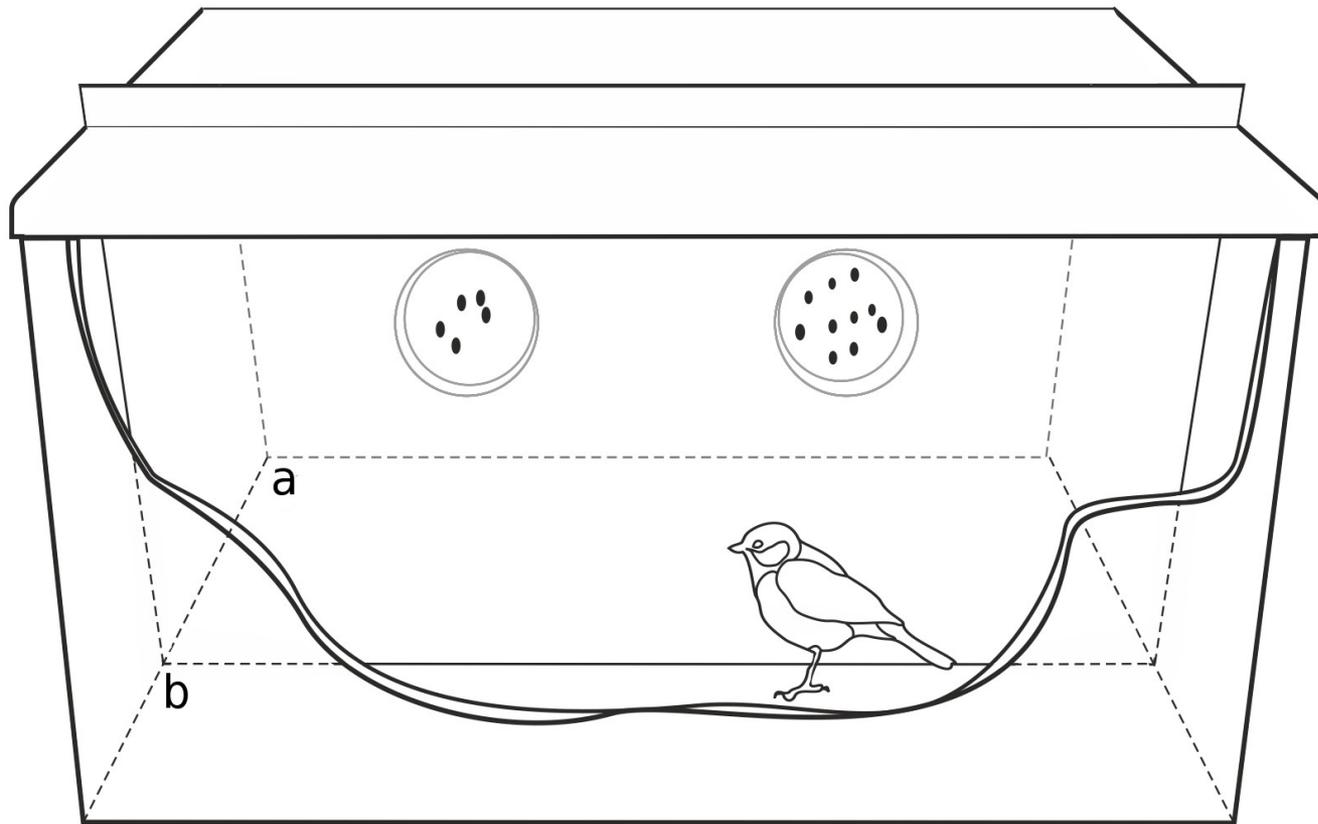

# Feeding with a dangerous prey

Field striped mice always tend to prefer the smaller quantity of a dangerous prey.

Pantelleva *et al*, 2013

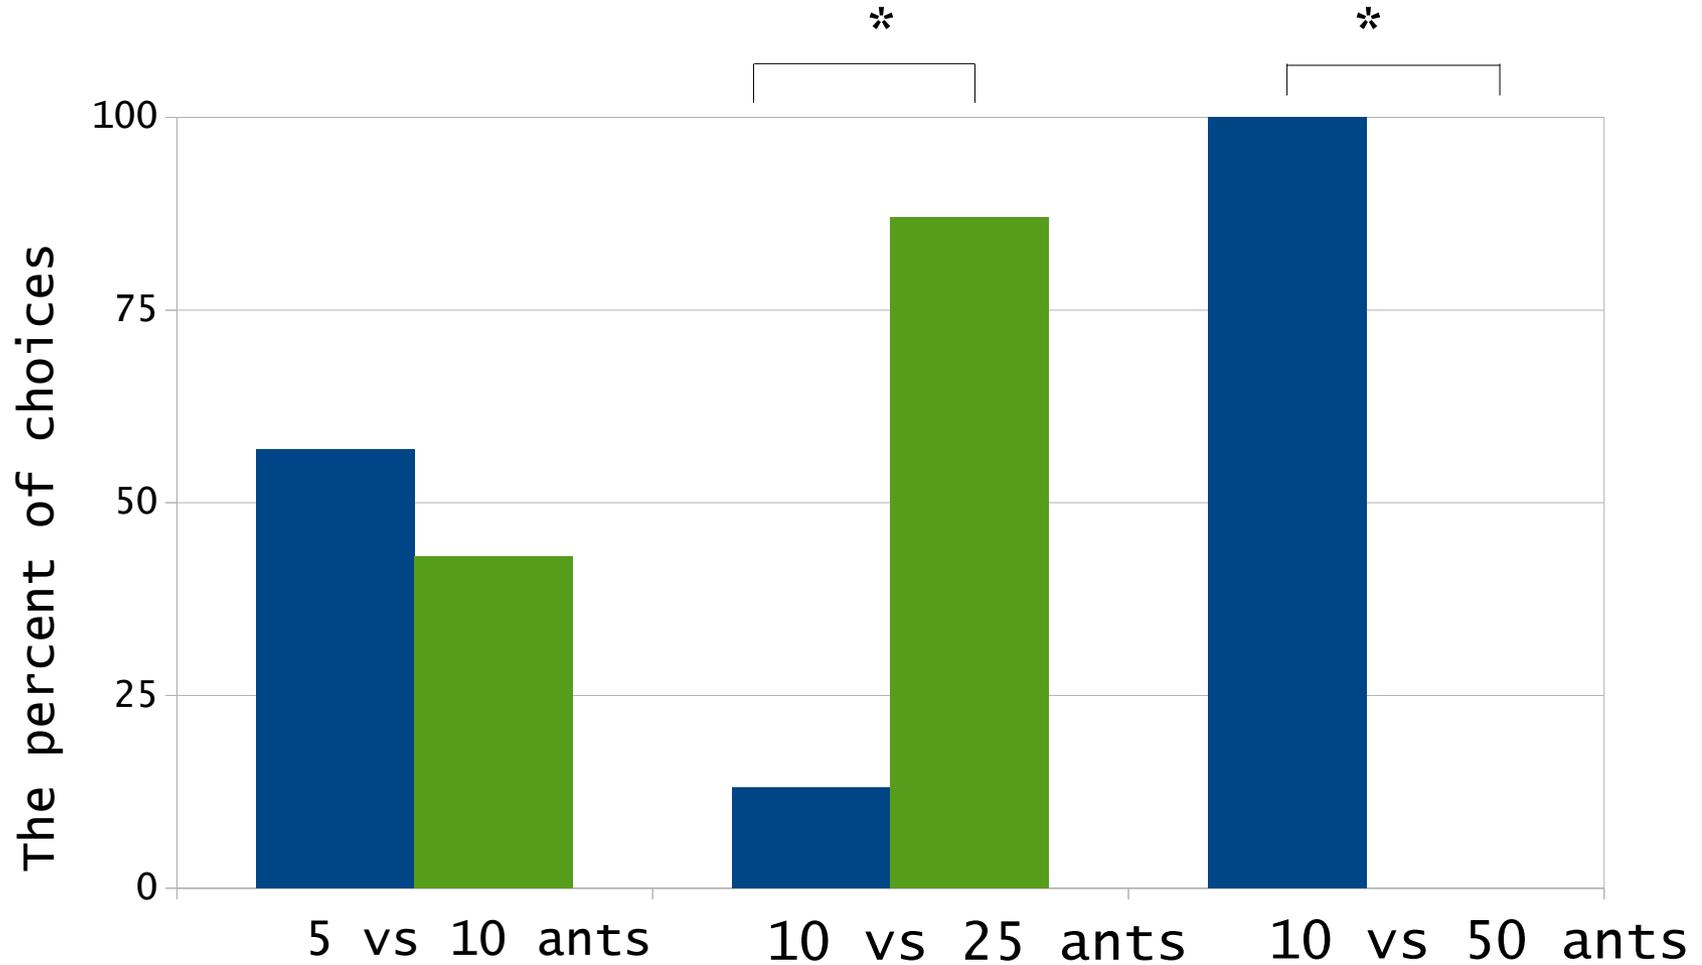

# Experimental design

1st experiment: 5 birds, 20 hours of video

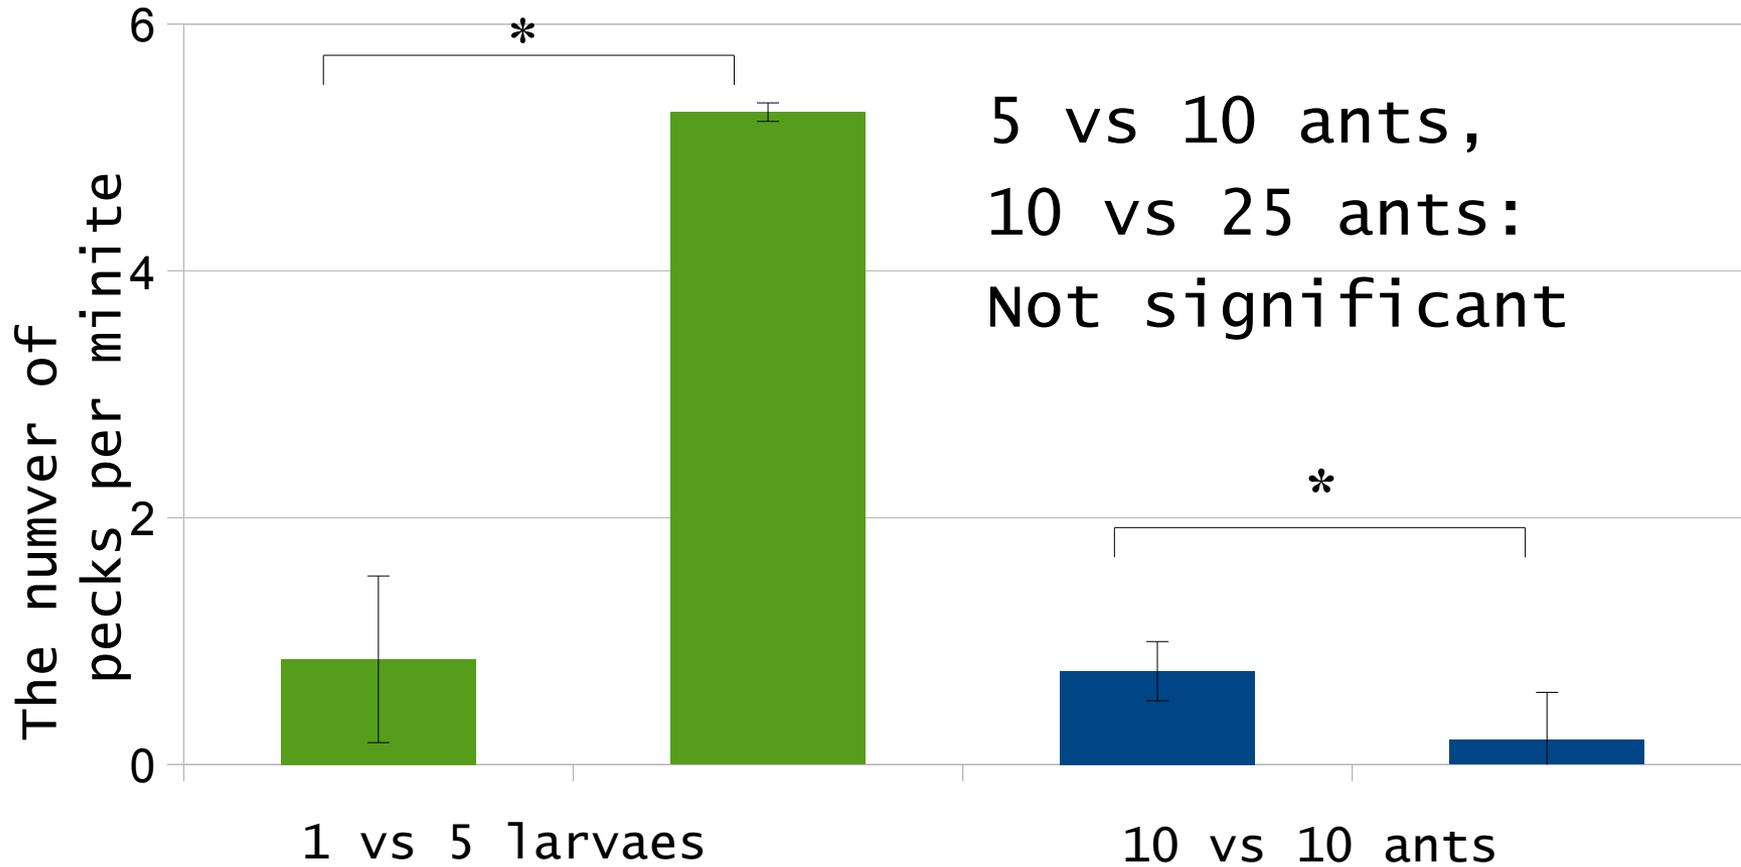

2nd experiment: 8 birds, over 40 hours of video

# 1<sup>st</sup> experiment: great tits go for less

The percent of choices of the feeders by tit  
(\*P < 0.05 Pearson's chi-squared test)

## 2<sup>nd</sup> experiment: great tits peck the less one

The number of pecks of the feeders  
cover per minute

(\*P < 0.01 Mann-whitney test).

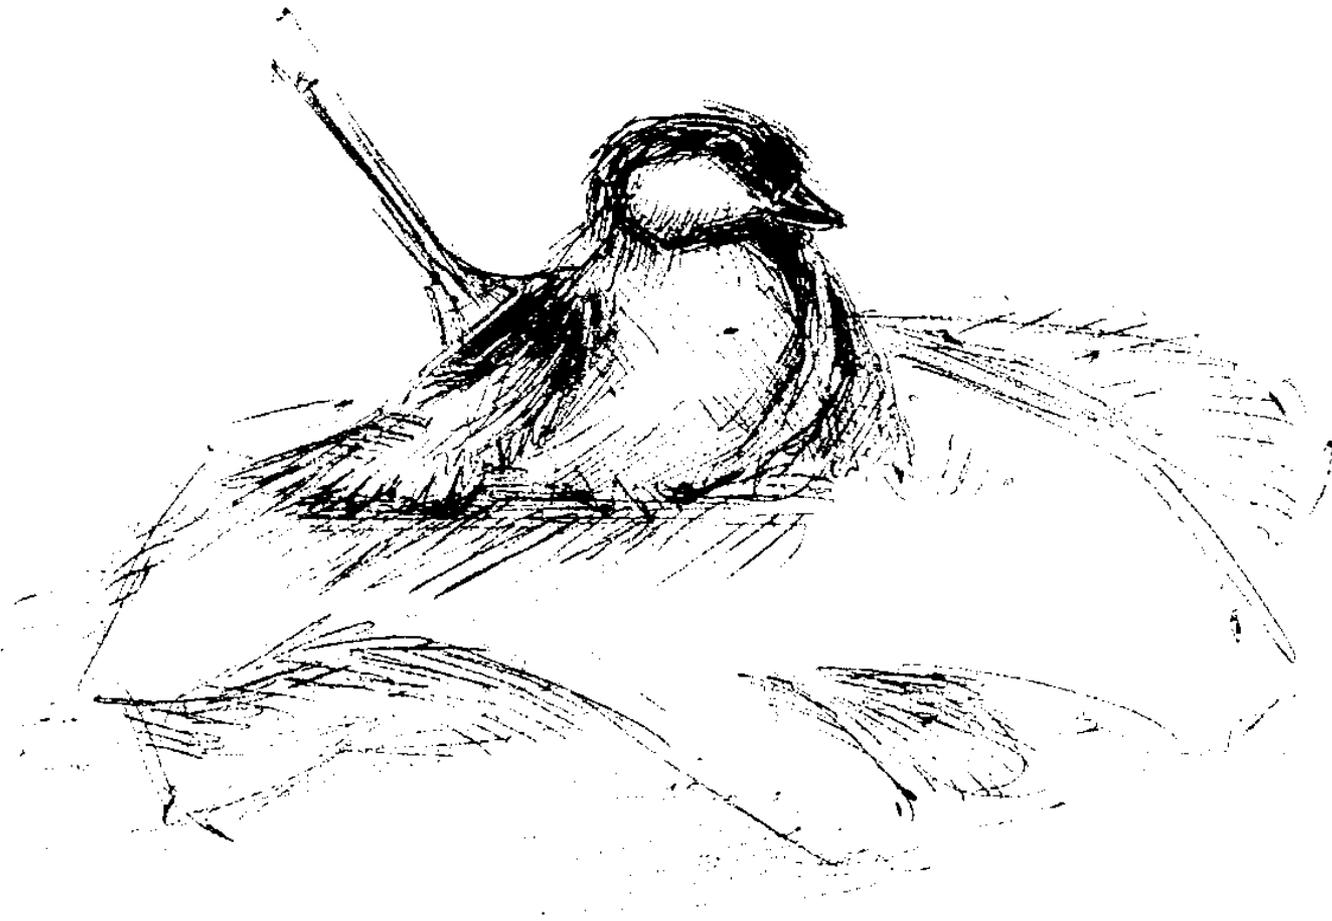

# 3<sup>rd</sup> experiment: first neutralize then eat

Time spend on hunting behaviour and handling in relation to the number of ants in the section

# Conclusions

- Feeding with a dangerous prey requires making choices by comparing the energy value and a danger level of prey.
- Great tits can distinguish between quantities of dangerous food items and make their decision cautiously basing on risk/reward evaluation, permitting a "reasonable violation" of optimal foraging laws.
